Feed Premix

The shell with a difference

The saying "*For every complex problem there is a simple solution.*" may be true in many general cases but proved to be wrong in particular cases of mineral nutrition of birds.

Mineral interrelationships are very complex. In view of the different purposes for which the birds are being reared, and with different ages and stages of production mineral requirements do vary a lot. Especially important are the *vital* macrominerals, **Calcium and Phosphorous**.

With so many calcium and phosphorous supplements being used, apart from the mineral mix, shell grit, DCP etc., the poultry industry is, naturally, expected to have no problems such as thin shelled eggs, broken eggs, shellless eggs, bone breakage problems, osteomalacea, rickets, etc. Unfortunately, the problems are quite common. This clearly shows that something is *missing* in Calcium - Phosphorous nutrition and the supplemented calcium and phosphorous are *not* being utilised properly.

Importance of Calcium and Phosphorous

Calcium is *essential* for proper bone growth in growing animals, bone maintenance in adults and shell production in laying birds. Apart from this Calcium is also *necessary* for blood clotting proper neuromuscular transmission and contraction of

muscle fibres. Absorption of Calcium from the digestive tract is adversely affected due to parasitic infestations, presence of oxalates and phytates in feed, higher levels of other cations such as Iron, Magnesium, Aluminium etc., and improper ratio of Calcium and Phosphorous. Calcium deficiency leads to drop in egg production and incidence of thin shelled and shellless eggs in layers and may lead to crippling, lameness and death. The Calcium deficient broilers will not be able to bear their own body weight on their limbs due to osteoarthritis. This may lead to starvation, loss in body weight gain and, sometimes, death. Also bone breakage is more during transport in Calcium deficient birds resulting in carcass rejection and economic losses.

Phosphorous has a very *vital* role to play in the energy metabolism of the body cells apart from its bone forming functions. Phosphorous is an integral part of various structural and functional components of the body such as cell membranes, membranes of organelle, nucleic acids, ATP molecules, etc. Phosphorous, as Cyclic AMP, functions as secondary messenger in intracellular communication and as phosphate buffer, maintains the homeostasis of the body fluids. Deficiency of Phosphorous results in retarded growth and rickets. Improper Calcium-Phosphorous ratio upsets the phosphorous absorption/metabolism and creates a deficiency. Phytate bound Phosphorous is not available to the birds as they lack the enzyme Phytase.

Magnesium is a vital divalent cation necessary for the birds. Both Calcium and Magnesium being divalent cations, there is a competition between them for absorption. Hence higher levels of Calcium in the diet increase the requirement of Magnesium. Neglecting this may possibly result in marginal Magnesium deficiency, stunted growth and lethargy in chicks and drop in egg production in laying birds.

Neocalcium granules contain Calcium and Phosphorous in the right ratio of 2:1, for proper absorption, metabolism and utilization by the bird. **Neocalcium** granules contain Magnesium in order to overcome the competitive effects of Calcium in diet and to maintain right body levels of Calcium, Phosphorous and Magnesium for proper bone growth, egg production and shell thickness. The base material fortified with peptide moiety aids in better absorption of Calcium from the digestive tract and proper mobilization from medullary bones during the shell formation process for better egg shells.

Composition (Each 5 gms contain):

Calcium - 1 250 mg ; Phosphorous - 625 mg ; Magnesium - 1.05 mg in a fortified base.

Uses : For thick egg shells, stronger bones, growth and production

Neocalcium

Granules

The breakthrough that helps your eggs won't break through
